NASA Carbon  
Monitoring System

# Background

High mountains over the Western US has high biomass and the potential for terrestrial carbon storage

Hypothesis: GPP can be improved if we put constrains on leaf nitrogen and soil moisture

Questions: Which observation constraint leads to the greatest improvement in GPP, where, at what time, and Why?

# Material and Setting

- Community Land Model

release-cesm2.2.01, 1 deg by 1 deg, 2003-01-01 to 2010-12-31, CAM4 reanalysis, 80 ensemble

SIF module in CLM [Li et al \(2022\)](#)

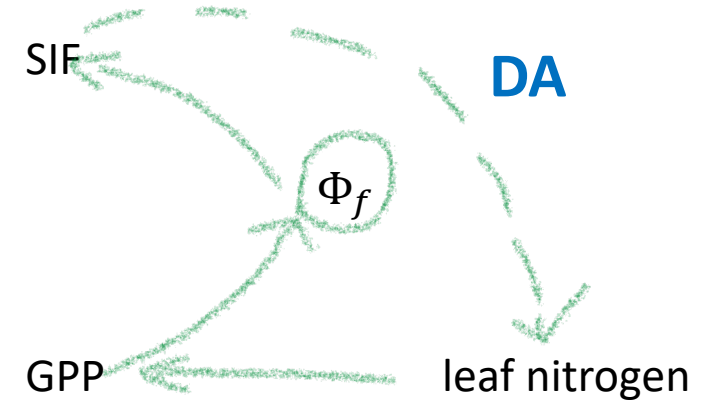

Method — SIF simulation

Leaf-level SIF emission:  $APAR \cdot \Phi_f$

Total SIF emission :  $SIF_{em} = \int_c APAR \cdot \Phi_f$

Observed SIF :  $SIF_{obs} = f_{esc} \cdot SIF_{em}$

$SIF_{em}$  : total emitted SIF  
 $APAR$  : absorbed photosynthetic active radiation  
 $\Phi_f$  : leaf-level fluorescence yield  
 $SIF_{obs}$  : observed SIF  
 $f_{esc}$  : escape probability, the probability an emitted SIF photon reaches the sensor

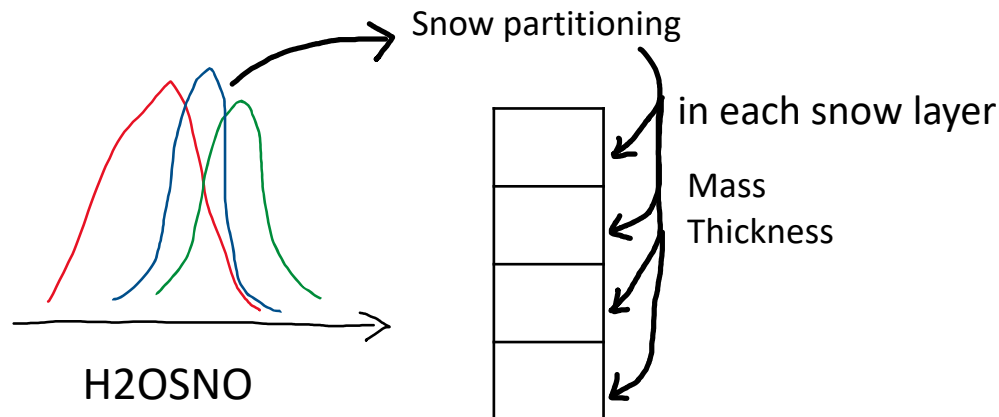

- DART (Data Assimilation Research Testbed)

Observation :

SNODAS daily SWE  
 Harmonized monthly SIF

Assimilation frequency:

daily for SWE DA  
 monthly for SIF DA

# SWE DA Challenge: There are some issues with snow input and snow melting

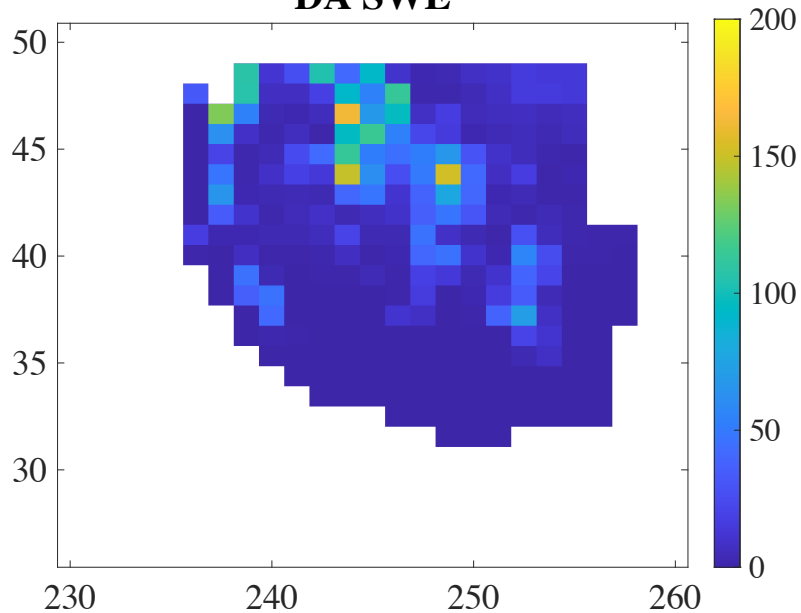

# Despite challenges with snow input and melting, DA successfully corrects Snow Water Equivalent over the Western US

**Free SWE**

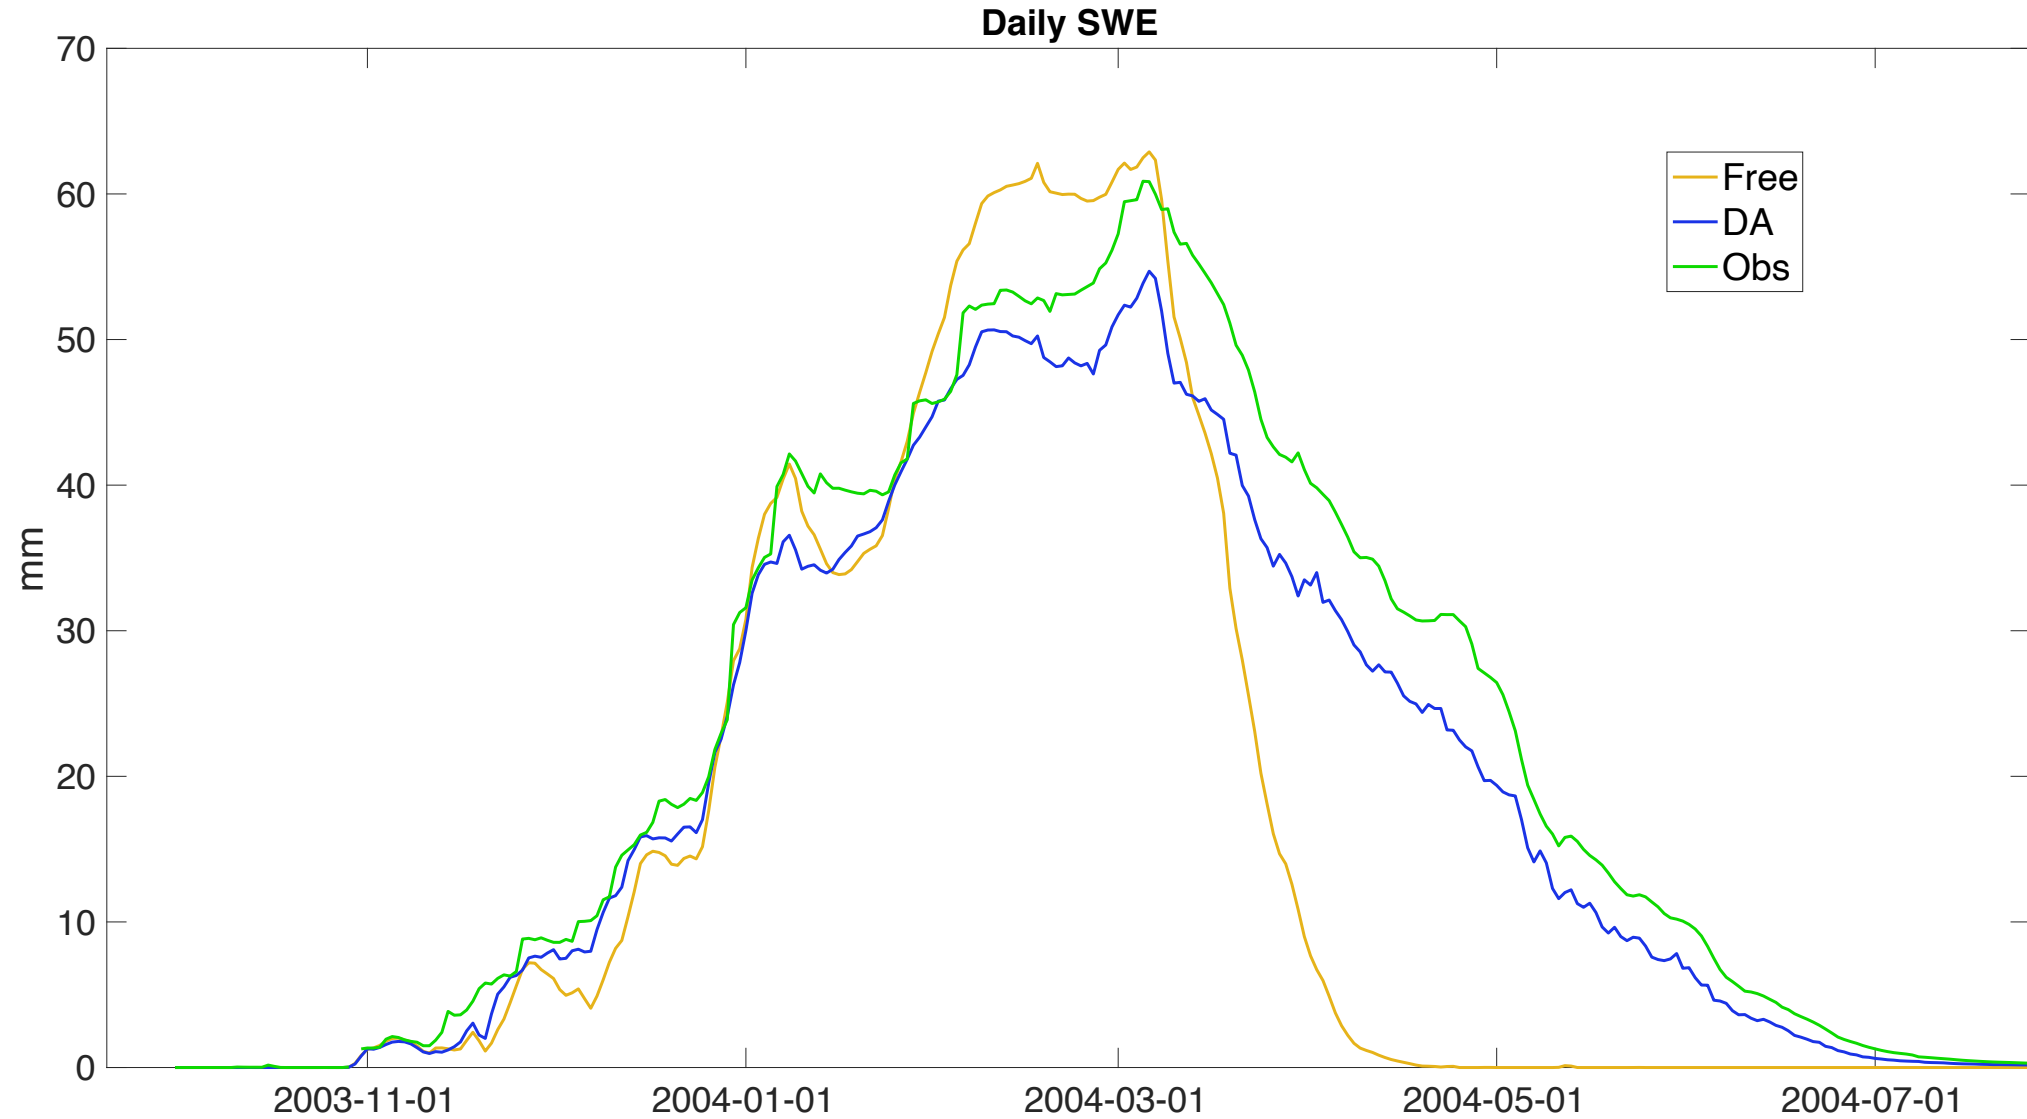

**DA SWE**

**SNODAS SWE**

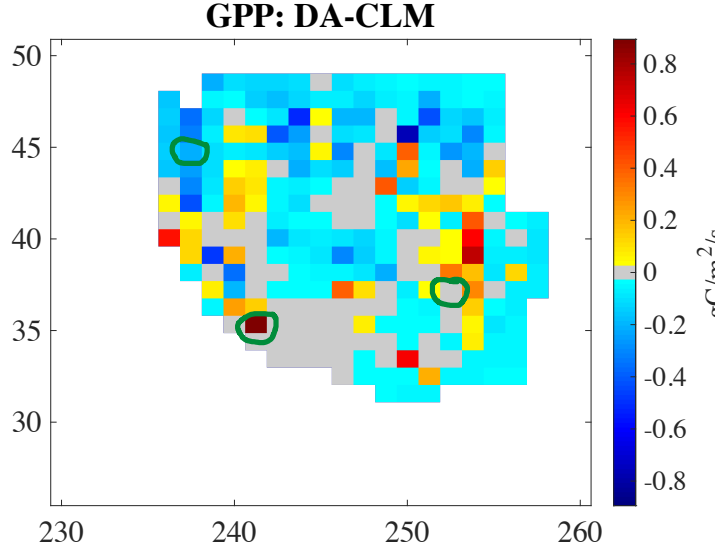

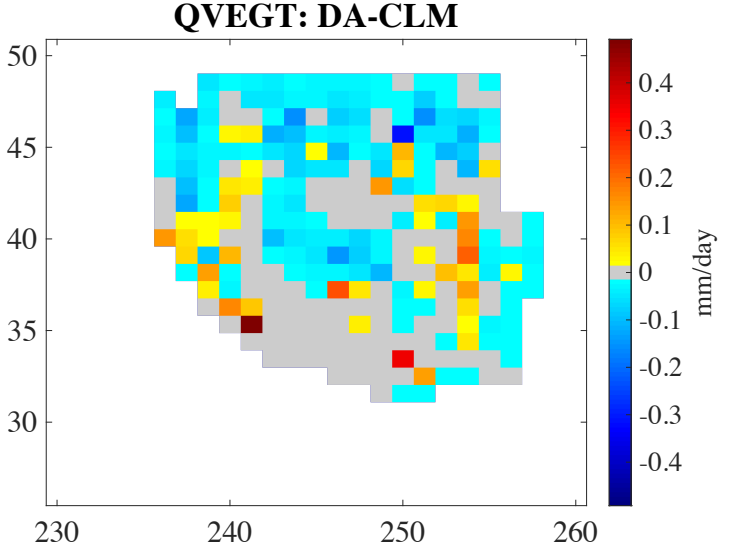

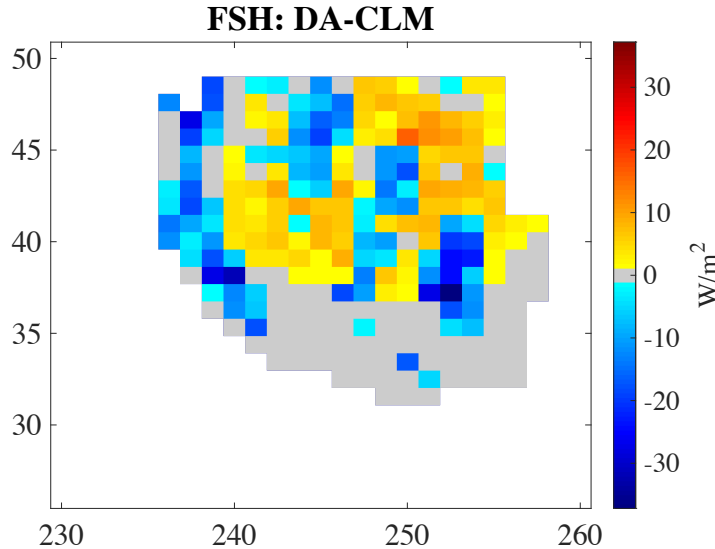

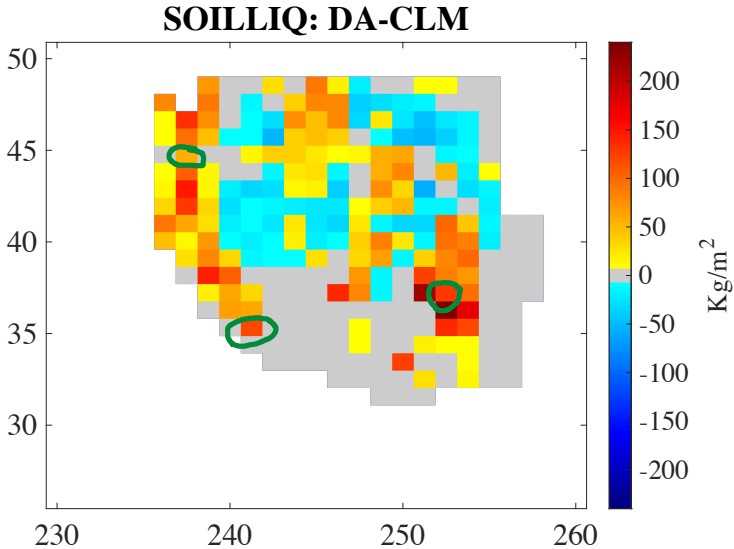

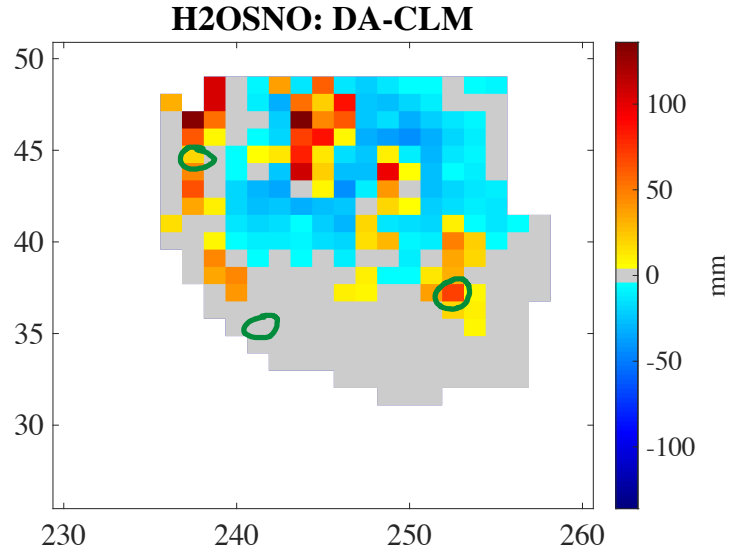

# Despite challenges with snow input and melting, DA successfully corrects Snow Water Equivalent over the Western US

In contrast to the significant change in SWE, the regional average of GPP in the Western US changes very little

# In regions where SWE increases, soil moisture increases but GPP responds differently

# GPP responds differently depending on whether it is water-limited or limited by other environmental factors

Sierra Nevada

Cascade Range

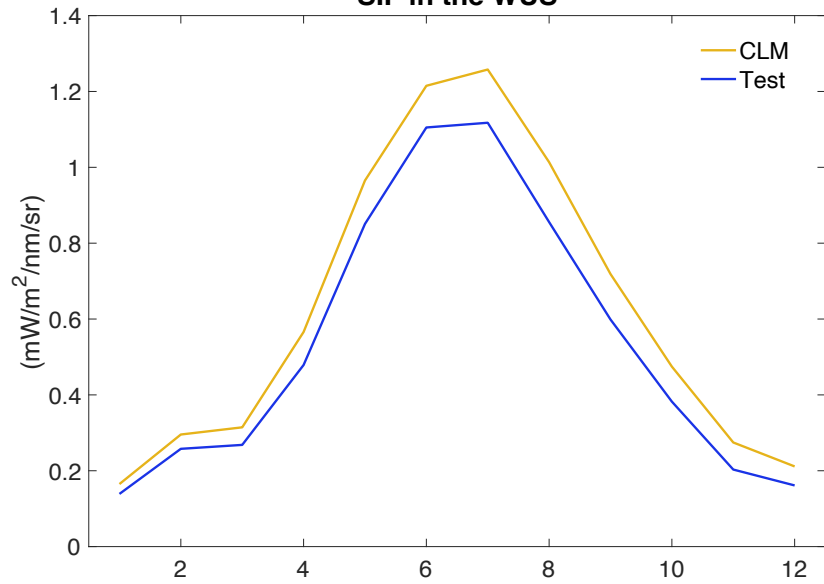

Southern Rocky

# GPP is sensitive to the change of leaf nitrogen

**SIF in the WUS**

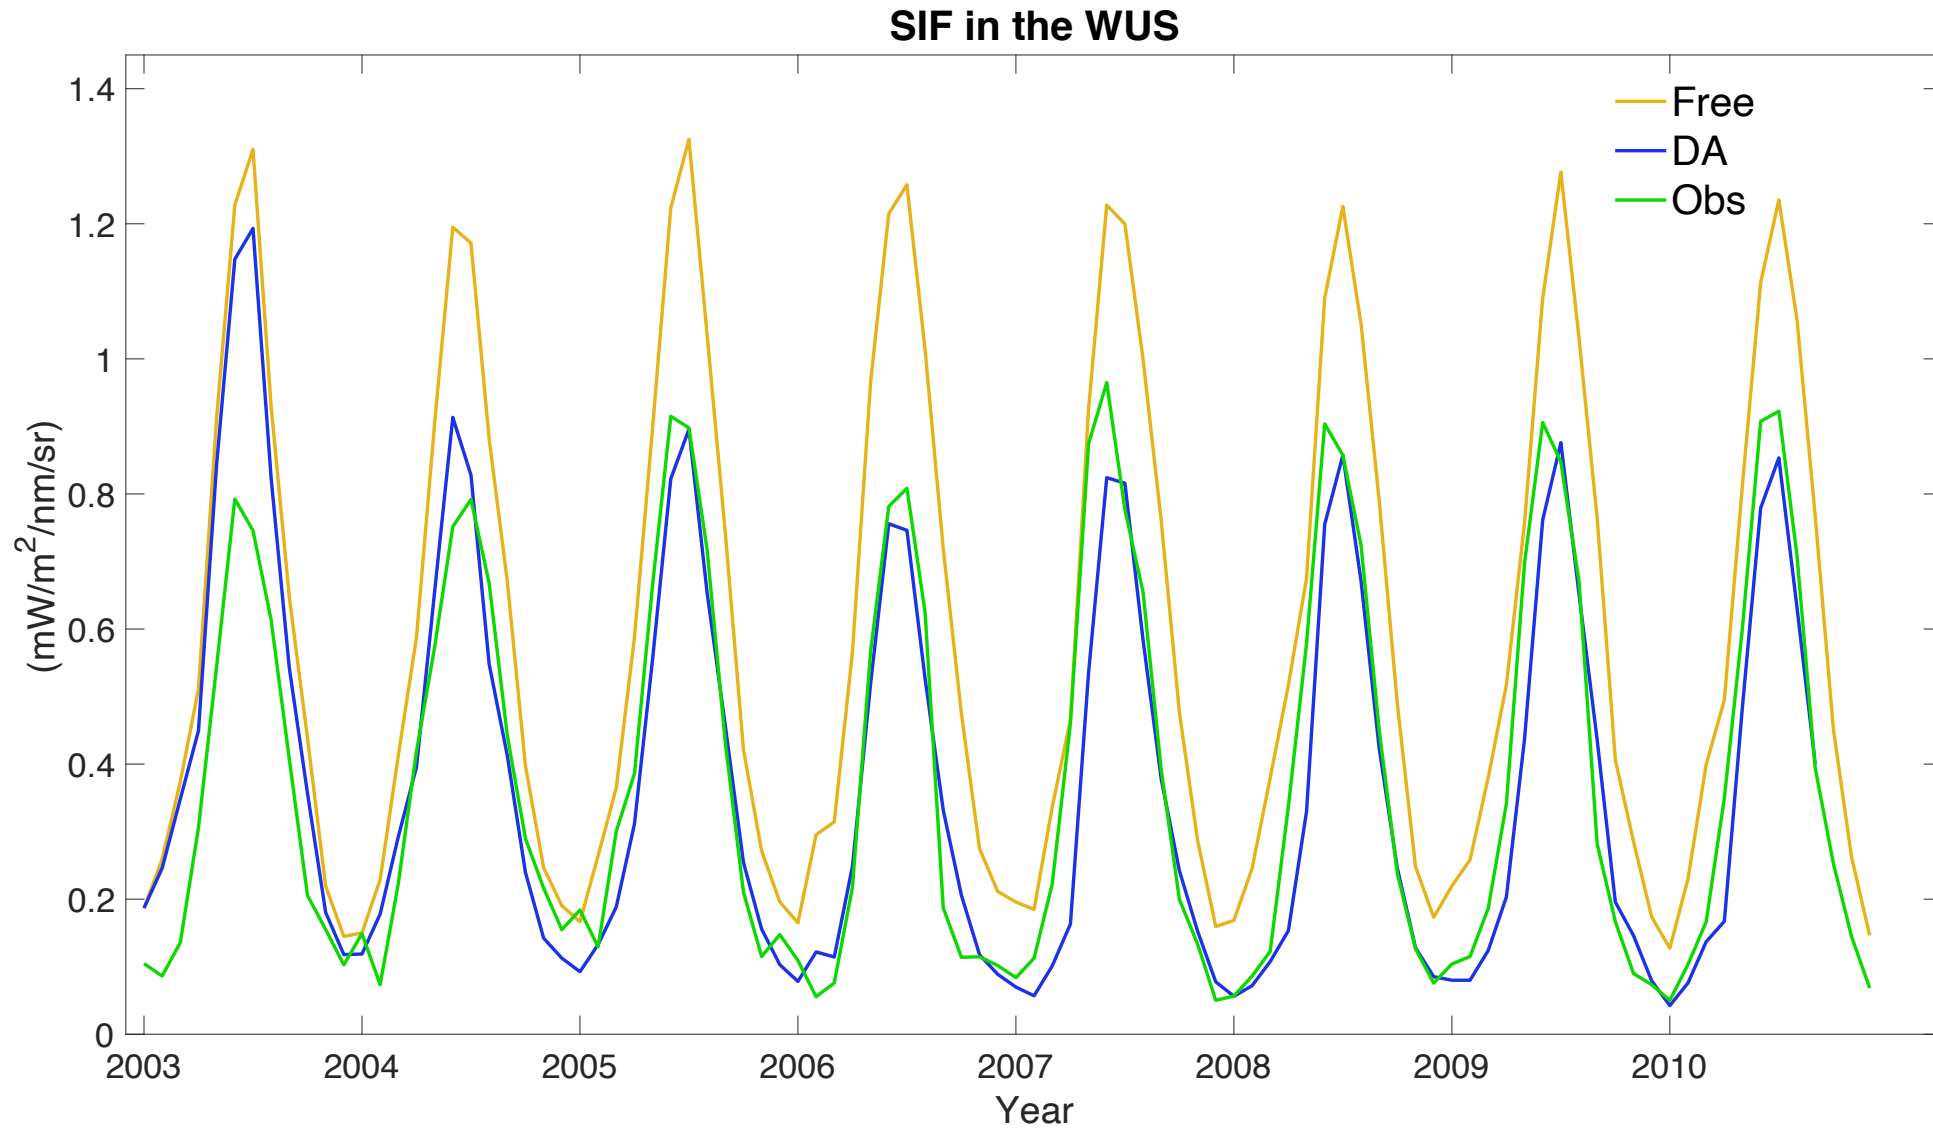

**LEAFN in the WUS**

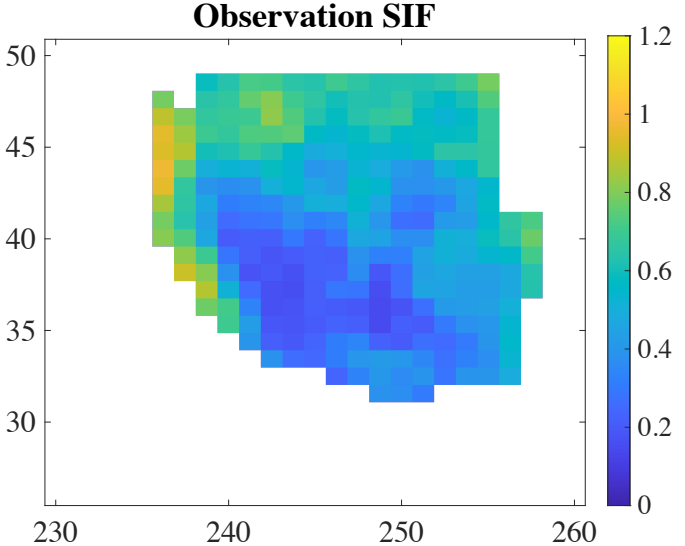

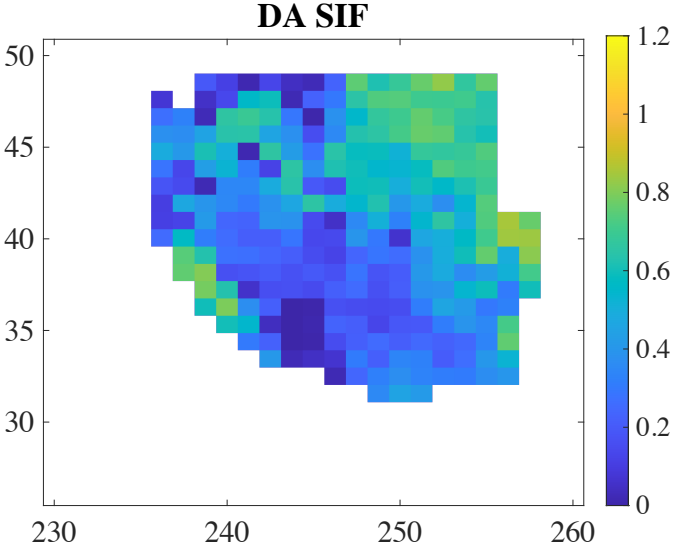

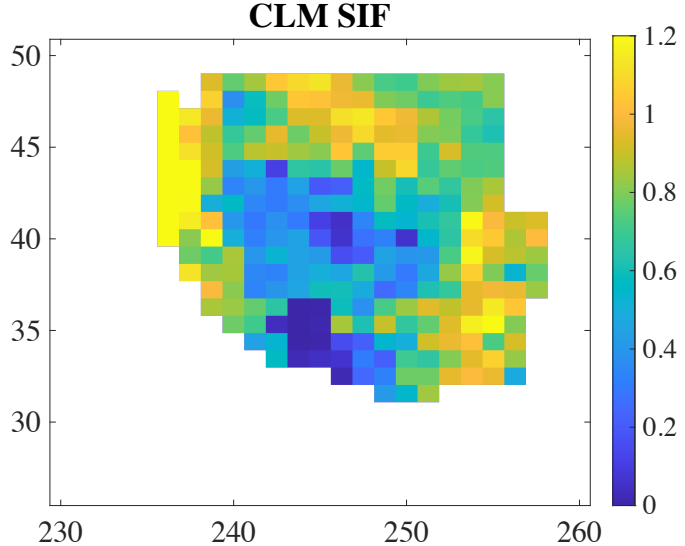

**GPP in the WUS**

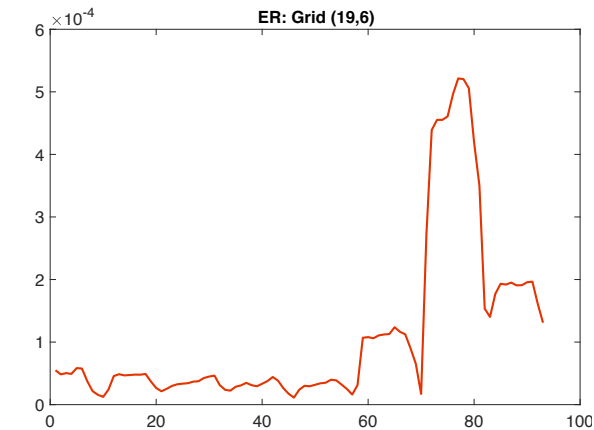

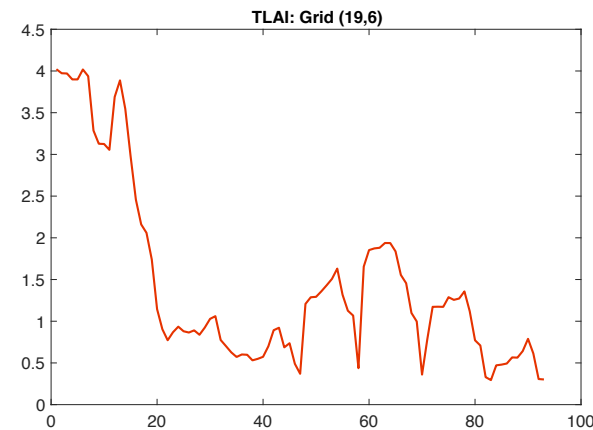

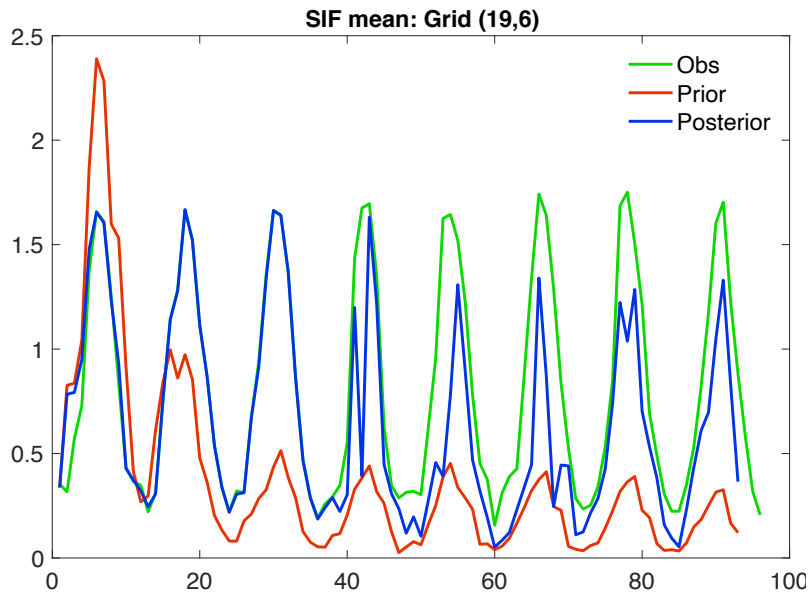

Though the regional average of SIF aligns well with the observation,

Though the regional average of SIF aligns well with the observation, SIF is overcorrected along the Cascade Range and in Montana

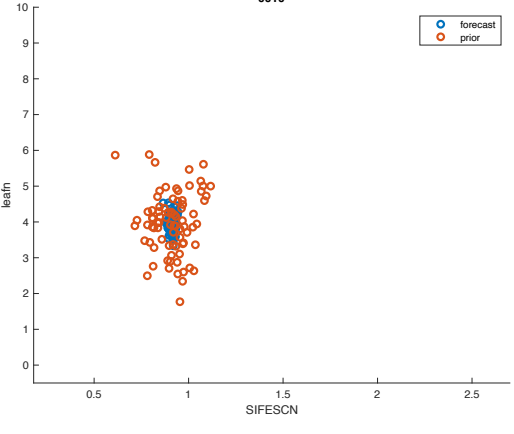

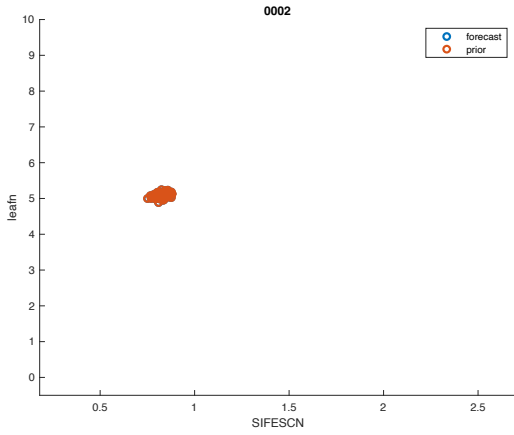

# When DA keeps pulling up SIF, leaf nitrogen is raised to an excessively high level

# Some DA options can be tuned to keep leaf nitrogen within the reasonable range

Leaf nitrogen

# Tune DA options to keep leaf nitrogen within the reasonable range

# Trying to understand why the increase in leaf nitrogen causes leaf carbon to decrease with the FUN turned on

# Summary

SWE DA changes the seasonality of GPP due to the impact of swe change on soil moisture and snow depth

Need to refine the way of leaf nitrogen altered by DA to effectively impact GPP
